Thoughtful Leadership

The AI Masterclass for Policymakers in Lagos offered a glimpse of what future-ready governance could look like. Held on 18 November at the Protea Hotel, Ikeja, the programme brought together senior officials from key Lagos State ministries (Economic Planning & Budget, Innovation, Health, Agriculture, Education, Information, Women Affairs, and Civic Engagement) for a full day of structured, hands-on learning on artificial intelligence.

Delivered by Qhala Kenya in partnership with Data Science Nigeria (DSN), the masterclass focused on building executive-level literacy across four core areas: AI foundations, ethical risks, governance models, and policy implementation. The goal was to equip decision-makers with enough understanding to ask the right questions, evaluate risks, and design realistic policies.

Participants were introduced to core AI concepts (machine learning, deep learning, large language models, agentic AI) and African use cases in agriculture, health, governance and smart cities. This was followed by structured discussions on bias, surveillance, deepfakes and child protection, framed as a debate on innovation versus regulation. A practical policy-simulation exercise on AI in Lagos transport was conducted, requiring officials, working in mixed stakeholder groups, to draft policy responses, negotiate trade-offs, and confront real implementation constraints.

What set this masterclass apart was the intentional cross-national partnership. Qhala Kenya brought pan-African expertise in responsible AI and policy design through its “Catalysing Africa’s Digital Future” programme; Data Science Nigeria (DSN) brought local credibility, technical depth, and a vision to develop one million AI talents. Together, they created a uniquely grounded space where senior officials could ask naive questions without judgment, challenge assumptions, and practise AI policymaking.

Participants left with sharper AI literacy, clearer mental models of where AI could help or harm in their sectors, and a more grounded sense of what responsible AI governance might look like for Lagos and, by extension, other Nigerian states. More importantly, the masterclass proved a simple but powerful point: if African governments are to govern AI well, they must first learn AI well, not at conference podiums, but in rooms where they can think, debate, and simulate the reality of policy making.

Omnilingual ASR is a new open-source speech recognition system that can automatically transcribe speech in more than 1,600 languages worldwide, including major Nigerian languages such as Yoruba, Igbo, Hausa and Edo, alongside hundreds of other African tongues. It is built around a massively scaled wav2vec-style encoder with up to 7 billion parameters, trained on roughly 4.3 million hours of multilingual audio, and paired with two decoding options: a classic CTC decoder for speed and an LLM-inspired decoder (LLM-ASR) for maximum accuracy. This architecture delivers state-of-the-art performance across a truly global language set, achieving character error rates below 10% for around three-quarters of supported languages, an accuracy level that was previously out of reach for many low-resource languages.

What makes Omnilingual ASR especially powerful for countries like Nigeria is that it is designed for extensibility, not just for a fixed list of big languages. Rather than requiring massive labelled datasets and specialised compute, it supports a bring-your-own-language approach: communities can supply only a small number of audio – text examples and still achieve usable transcription quality through in-context learning. Underpinning this is the Omnilingual ASR Corpus, a commissioned dataset covering roughly 350 underserved languages collected through paid partnerships with local organisations and

released openly as one of the largest ultra-low-resource spontaneous speech resources to date. The models themselves come in sizes from about 300M to 7B parameters, with open code and checkpoints, making it feasible to run speech recognition from mobile or edge devices up to full cloud deployments.

Beyond benchmark numbers, Omnilingual ASR is a clear statement about linguistic justice in the age of AI. Traditional commercial ASR systems typically support perhaps 50–120 mainly high-resource languages, leaving thousands of communities especially in Africa effectively voiceless in digital systems and products. By deliberately targeting the long tail and building ethical design choices into its process (community partnerships, fair compensation for native speakers, and open datasets and models), this work shifts speech recognition from a privilege reserved for a few global languages towards shared digital infrastructure that can, in principle, belong to everyone. For Nigerian builders, it opens the door to voice interfaces, transcription tools, accessibility solutions and language-preservation projects that treat Yoruba, Igbo, Hausa, Edo and many others as first-class citizens in the AI ecosystem, not afterthoughts.

Visit their official website to explore the language datasets: [here](#)

Google debuts Nano Banana Pro, a Gemini 3-powered AI model that generates studio-quality

images

Google released two interconnected innovations: Gemini 3, its next-generation large language model, and Nano Banana Pro, a Gemini-3-powered enterprise-grade image-generation and editing tool. On the surface, these are incremental product iterations. In substance, they reveal a strategic pivot that will reshape work and creativity across Nigeria and beyond.

Gemini 3 is designed for agentic workflows which are systems that do not merely chat but autonomously take actions. It can write and execute code, make API calls, retrieve information and iterate. Critically, it is being integrated directly into Google Workspace, meaning every organisation using Docs, Slides, Gmail and Chat will soon have agentic AI capabilities switched on by default. For businesses, the implication is immediate: an AI assistant that drafts emails, writes code snippets, creates presentation decks and handles routine tasks. Some organisations will welcome this; others will confront anxiety about control, security and job displacement.

Nano Banana Pro is designed for the opposite end of the creative spectrum in that it is brand-safe image generation for enterprises. It allows users to upload brand kits (colour palettes, logo guidelines, fonts) and generate images that strictly adhere to brand rules. It

supports style references, meaning a designer can show it an example image and instruct it to generate variations matching that aesthetic.

For creative agencies, this combination is a double-edged sword. On one hand, Nano Banana Pro makes it possible for a small agency to generate localised marketing assets for clients at a fraction of the cost of hiring human designers. On the other hand, it commodifies design work and directly threatens employment for junior designers and junior creatives in the advertising and marketing sectors. The skill required shifts from “can you create a design” to “can you write a good prompt and curate AI outputs” a narrower skill set that requires fewer people.

What Google is fundamentally doing is creating a consumerised version of a service that was previously only available to large enterprises with dedicated AI teams. The real value migrates to whoever controls the next generation of the model.

Stack Overflow Pivots Toward Becoming an AI data provider

Stack Overflow was built on as a collective good, a place where developers ask questions and share solutions, freely accessible to anyone with internet access. For two decades, it has been one of the world's most-visited websites precisely because the community norms were transparent: contribute knowledge, help others, keep the platform open and ad-light.

This November, Stack Overflow announced it was transitioning toward becoming an AI data provider. The platform is now licensing its archive of millions of coding questions and answers to companies training large language models. The contributors who built that knowledge base did so under the assumption it would remain a public resource. Now, their work is being repackaged as a proprietary data product enriching the platforms licensing it (OpenAI, Anthropic, etc.) and the platform selling it (Stack Overflow itself). The original contributors see minimal direct benefit.

This signals a broader fragmentation of the open web that developers relied on. The platforms and tools you learned on are becoming data brokers in the AI economy. This shift calls for developers to embrace AI-assisted development, not just classical programming, because the bot writing code for you is now trained on Stack Overflow data; contribute to open-source projects with explicit governance around data use; and be cautious about signing away intellectual property rights when using closed platforms.

Nigeria Demands Global Equity in AI Governance at G20 Summit

The 2025 G20 Leaders' Summit in Johannesburg last month was historic for one reason that transcended the usual diplomatic norm as the world's most powerful economies met on African soil, and Africa walked out having fundamentally rewritten the terms of negotiation. South Africa's delegation, led by President Cyril Ramaphosa, had chosen the philosophical framework of Ubuntu "I am because we are" to anchor the gathering. This was no accident. It signalled that the Global South was not attending the G20 as a supplicant, but as a co-architect of global governance.

Nigeria's intervention, led by Vice-President Kashim Shettima on President Tinubu's behalf, articulated a doctrine that is already reshaping how the continent will approach AI, infrastructure and resource governance for the next decade. The doctrine is simple: value addition at source.

Here is what that means in practice. Nigeria demanded that the minerals powering the AI revolution (cobalt, lithium, tantalum, etc.) cannot be extracted from African soil, processed overseas, assembled into GPUs in Taiwan, and sold back to Africa at inflated prices. Instead, Nigeria called for binding global frameworks that ensure local processing, technology transfer, and contractual guarantees that compute capacity and manufacturing stay within Africa as resources are extracted.

On artificial intelligence itself, Nigeria's position was equally uncompromising. The nation argued that AI systems exported to Africa cannot be permitted to automate away millions of jobs in customer service, data annotation and basic accounting sectors vital to African workers' livelihoods. It demanded that global ethical standards for AI require companies to test models against African demographics and languages before deployment, because current systems routinely misclassify African faces and misunderstand African contexts. Most radically, Nigeria insisted that the Global South's voice must carry equal weight in shaping AI governance, not merely sit in the audience whilst wealthy nations dictate the rules.

The final Leaders' Declaration, agreed despite US tensions, committed the bloc to an "AI for Africa Initiative" that pledges multilateral support for sovereign AI compute capacity within African countries, the creation of representative African datasets, talent hubs to prevent brain drain, and equitable technology transfer. It also adopted a Critical Minerals Framework ensuring that mineral-endowed nations (Nigeria included) capture greater value from extraction and retain it for inclusive economic growth.

For Nigerian builders, policymakers and investors, the implication is concrete: multilateral capital is now flowing toward African infrastructure, and Nigerian regulators will feel emboldened to ask tougher questions of foreign tech companies regarding data residency, local model

Backbone Connectivity Network (BCN) launches a multi-tenant AI cloud in Nigeria

Backbone Connectivity Network (BCN), the national wholesale fibre provider, has partnered with Zadara and Touchnet to launch what it calls Africa's first "neutral multi-tenant AI cloud" or "AI factory" effectively a co-working space for compute, where multiple companies and researchers can rent sliceable GPU power hosted entirely within Nigeria.

Until now, Nigerian startups and teams have had only one option: rent expensive GPU time from AWS or Google Cloud, pay in dollars, deal with latency and comply with sending sensitive data abroad. BCN's AI Factory changes that equation. Using NVIDIA-aligned infrastructure deployed on BCN's national backbone, the platform allows teams to train models, run inference workloads and build AI products entirely on Nigerian soil, priced in Naira.

The "multi-tenant" architecture is the genius part. Instead of one company owning an entire server, multiple customers share the same GPU cluster securely, dramatically reducing the unit cost of compute and making training economically viable for teams that previously could not afford it. For Nigerian fintechs handling customer data, government agencies processing citizen information, and universities conducting research, the value is stark: compliance with data residency rules, latency elimination for real-time applications, and cost savings that could reach 30–50%

compared to US clouds.

The open question is adoption. Success depends on whether the Nigerian tech ecosystem embraces BCN's platform or defaults to the familiar comfort of overseas clouds. The collective action problem is real one company taking on new infrastructure risk is riskier than all of them adopting it together. But if this launch gains traction, it represents the first credible alternative to US cloud dominance for AI development in Nigeria.

TD Africa and Schneider Electric Sign MoU to Build AI-Powered Data Centres in Nigeria

Data centres have long been Nigeria's infrastructure Achilles heel. Power constraints, limited skilled operations teams, and outdated facilities have meant that most critical Nigerian digital services are hosted abroad. This November, that shifted when TD Africa, the veteran ICT distributor, signed a memorandum of understanding with Schneider Electric, the global power and infrastructure giant, to build a physical network of AI-ready data centres across Nigeria.

The term "AI-ready" is deliberate and significant. Traditional data centres are engineered for servers running at modest power densities. AI infrastructure, racks of GPUs drawing 10–50 kilowatts per server and generates torrential heat. Cooling becomes the primary operational and economic challenge. Schneider Electric's expertise is precisely this: liquid cooling systems, intelligent power distribution, and AI-driven predictive maintenance that optimises energy consumption in real time.

The MoU language hints at a modular, scalable approach. Rather than a single monolithic facility, TD Africa and Schneider are likely planning "plug-and-play" data centre units that can be deployed at tech hubs, university campuses and special economic zones, bringing compute power closer to where it is needed and reducing the capital barrier to entry.

For Nigeria's digital economy, the implications are immediate. First, resilience: Nigeria's grid is unpredictable, but Schneider's systems integrate solar, battery storage and grid power seamlessly, making AI facilities dramatically more reliable than traditional offices. Second, cost: AI-powered energy management can cut data-centre electricity costs by 20–30%, a monumental saving in a market where power is expensive and unpredictable. Third, jobs: operating modern data centres demands engineers skilled in infrastructure automation, thermal management and predictive analytics skills that are scarce in Nigeria but trainable.

Memlayer 0.1.8 Python Library Launches, Bringing Plug-In Persistent Memory to Any LLM

Current large language models suffer from a fundamental flaw which is amnesia. Once a conversation ends, the model forgets everything about that user. If you chat with a customer service bot today and again next month, the bot has no memory of your previous interaction.

In November, Memlayer 0.1.8 launched as an open-source solution to this constraint. It is a “memory layer” that sits between your application and an LLM, storing and retrieving user preferences, past interactions and contextual facts in a structured, persistent way.

For developers building customer-facing products, this is transformative. Imagine a fintech customer service bot that remembers a customer’s previous complaints and proactively offers solutions. Imagine a learning platform that remembers a student’s weak topics over a whole semester and tailors content. Imagine a health app that tracks a patient’s medical history and alerts when patterns emerge. Without Memlayer, each of these requires custom engineering work. With Memlayer, developers can add sophisticated memory in minutes.

But there is a compliance trap. If an AI system is remembering personal data, your application now has privacy and data-protection obligations under Nigerian law and any international compliance regimes (like GDPR

if you handle EU citizens’ data).

Builders need to think carefully about encryption, access control, audit trails and users’ right to be forgotten, topics that regulators and civil society will increasingly scrutinise as AI becomes embedded in everyday services.

Salesforce Introduces Agentforce Observability for Deeper AI Insight

Salesforce, the CRM platform used by most large Nigerian companies, has launched Agentforce Observability, a suite of tools to monitor and debug AI agents deployed in customer interactions.

The Salesforce logo, consisting of the word "salesforce" in white lowercase letters inside a blue cloud shape.

When you deploy an AI agent to handle customer calls, emails or chats, you risk it saying something offensive, making an incorrect promise, or violating a compliance rule. You have imperfect visibility into why it made a particular decision.

Agentforce Observability acts like a flight recorder for your AI operations. It logs what the agent thought (its reasoning chain), which data it looked up, which rules or guardrails it applied, why it reached a conclusion, and when it deviated from expected behaviour. Customer service teams can then audit these interactions, spot patterns, identify training needs and continuously improve system performance.

This creates a new job category, "AI Compliance Analyst". Companies serving global clients especially US and EU firms with stringent AI governance requirements will

increasingly need staff who can audit AI interactions, spot fairness and safety issues, and ensure compliance. It lifts the entire operation from "deploy and hope" to "deploy, monitor, iterate and optimise." For Nigerian business process outsourcers and customer service teams, this is both a threat (AI is taking over some tasks) and an opportunity (new skilled roles are emerging).

Finland's NestAI Secures €100M and Joins Forces with Nokia on Defence-Focused AI

Finnish startup NestAI raised approximately €100 million to develop defence-grade artificial intelligence systems in strategic partnership with Nokia, the Finnish telecoms and infrastructure giant. NestAI's focus is on building robust, offline-capable AI systems designed to operate in harsh, disconnected environments where traditional cloud-based AI fails. These are systems that can function without constant internet connectivity, that degrade gracefully when bandwidth disappears, and that prioritise security and resilience over raw computational power. Paired with Nokia's expertise in telecommunications infrastructure and defence-grade networking, the partnership is aimed at creating an integrated stack: secure communications networks, edge AI systems that run without central cloud access, and situational awareness tools that can operate in denied or degraded environments.

For Nigeria and other African nations, NestAI's trajectory illustrates several critical lessons. First, it shows how nations and firms can build competitive advantage in AI around specific operational constraints. Finland is not trying to beat Silicon Valley at building general-purpose foundation models. Instead, it is building AI specifically tuned to harsh, offline, security-critical environments. That specialisation is a legitimate path to global competitiveness.

Second, it demonstrates that defence-oriented AI investment drives advances that eventually spill over into civilian applications. Technologies initially developed for

military communications, drone coordination, battlefield logistics or cyber-defence eventually find use in civilian critical infrastructure, emergency response, and public safety. The technical innovations (robustness, security, offline-first architecture, edge computing) are universally valuable.

Third, it signals where the high-value contracts and strategic partnerships will emerge globally over the coming years. Nations and firms that control robust, offline-capable AI for security-critical infrastructure will have structural advantages in a world where supply chain fragmentation, climate shocks, and geopolitical tension make infrastructure vulnerability a fact of life.

Finland's NestAI is proof that a small nation, can build a world-class AI company by understanding its own constraints, building for them, and then scaling globally. Nigeria's constraints are different (security challenges, infrastructure fragility, economic volatility, etc), but they are equally real. The question is whether Nigerian entrepreneurs and policymakers will treat those constraints as liabilities to overcome, or as opportunities to specialise and innovate.

The Nokia logo is displayed in a large, blue, sans-serif font.A graphic featuring the logos of Nokia, NestAI, and Tesi. The Nokia logo is on the left, the NestAI logo (a stylized 'n' with 'NestAI' text below it) is in the center, and the Tesi logo is on the right. They are all in white against a dark blue background with a subtle gradient and a faint circular pattern at the bottom.

Paper: [Who Wrote This? Identifying Machine vs Human-Generated Text in Hausa](#)

Authors: Babangida Sani, Aakansha Soy, Sukairaj Hafiz Imam, Ahmad Mustapha, Lukman Jibril Aliyu, Idris Abdulmumin, Ibrahim Said Ahmad, Shamsuddeen Hassan Muhammad

This paper tackles the rising challenge of distinguishing human-written text from AI-generated content in Hausa, a major West African language that is still under-represented in NLP research. With modern language models increasingly capable of producing fluent Hausa text, the authors highlight that standard detectors mostly trained on English perform poorly when applied to Hausa due to cultural, syntactic, and code-mixing patterns they were never exposed to.

To address this, the researchers built a labelled dataset containing both authentic Hausa writing and outputs generated by contemporary large language models. They then evaluated a range of models, including classical machine-learning baselines such as logistic regression and SVMs using n-gram features, as well as transformer-based classifiers fine-tuned on the Hausa dataset. The study also examined indicators such as perplexity-based scoring and embedding-based representations to test whether Hausa-specific linguistic patterns could improve classification.

Their findings show that off-the-shelf detectors struggled significantly confirming that models trained on high-resource languages do not generalise well to Hausa. However, fine-tuned transformer models, even relatively small ones, achieved far better performance once trained on Hausa examples, demonstrating that effective detection requires language-specific training data rather than generic multilingual resources.

Paper: [Deep learning and molecular dynamics reveal promising EZH2 inhibitors for epigenetic cancer targeting](#)

Authors: Damilola A Omoboyowa, Temitope C Aribigbola, Babasola Aiyeku, Damilola S Bodun, and Oluwatoba E Oyeneyi.

This paper investigates how artificial intelligence can accelerate the search for new cancer drugs by focusing on EZH2, a protein known to silence important genes and contribute to the growth of several cancers. Instead of relying on the traditional trial-and-error method of testing thousands of chemicals in the lab, the researchers used a deep-learning system to imagine thousands of possible drug molecules. They then ran advanced computer simulations to predict which of these molecules were most likely to attach firmly to EZH2 and stay stable, a key requirement for an effective treatment.

From this process, four standout candidates emerged, with one showing stronger predicted performance than Tazemetostat, the only approved EZH2-targeting drug currently in use. These early results suggest that AI can uncover fresh chemical designs that might avoid some of the limitations of existing drugs, such as reduced effectiveness or unwanted side effects.

Although the findings are still at the computational stage and require laboratory and clinical testing, the work demonstrates how digital tools can dramatically speed up the earliest and most expensive phase of drug discovery. By generating new drug ideas in a matter of days rather than years, this approach could help researchers develop more precise and powerful treatments for cancers driven by EZH2. Ultimately, the study highlights a growing shift in medicine: using AI not just to analyse data, but to actively design the next generation of therapies.

Paper: [Green Topics, Deep Roots: Energy-Aware Topic Modelling of Multilingual Nigerian Lyrics](#)

Authors: Sakinat Oluwabukonla Folorunso, Akerele Tosin Sina, Francisca Onaolapo Oladipo and Giwa Oluwakemi Rukayat

This paper presents an energy-aware approach to topic modelling tailored to the multilingual and culturally rich landscape of Nigerian music. Introduced at the NeurIPS 2025 Creative AI Track, the study investigates how to extract coherent thematic structures from lyrics written in English, Yoruba and Nigerian Pidgin, where code-switching and colloquial expression are the norm rather than the exception.

The researchers assemble an open-access Nigerian lyrics dataset and benchmark seven topic-modelling methods, ranging from classical probabilistic and matrix-factorisation models (LDA, HDP, NMF, LSI) to modern embedding-driven techniques (BERTopic, Top2Vec, GSDMM). Using metrics such as topic coherence, topic diversity, Jaccard similarity and estimated energy consumption, the study reveals a clear trade-off between representational depth and computational efficiency. Classical models especially non-negative matrix factorisation, deliver the highest topic coherence while consuming negligible energy, making them well-suited to short, sparse and code-mixed texts. Meanwhile, embedding-based models like BERTopic generate highly diverse and fully disjoint topic sets but at significantly higher energy cost.

The extracted themes highlight enduring cultural pillars of Nigerian music, spanning spirituality, relationships, everyday life, social commentary and community identity. By showing that lightweight, interpretable models can outperform more computationally intensive neural methods in low-resource settings, the work underscores the importance of Green AI principles for African NLP by prioritising sustainability, accessibility and cultural fidelity.

Ultimately, the paper demonstrates how AI can support creative and linguistic exploration without imposing prohibitive computational demands. It stands as a contribution to inclusive, culturally grounded AI research from Nigeria, reflecting a broader commitment to building technologies that respect both local contexts and global sustainability goals.

Opportunities and Events

An overview of upcoming events, available funding, proposal invitations, and other timely opportunities shared within the Community.

Lagos Impact Hackathon 2025

The Lagos Impact Hackathon (LIH) is a 48-hour venture-building hackathon that brings together technology leaders, Web3 innovators, and development partners to build practical, SDG-aligned solutions that can scale in the real world. The Hackathon runs through December 11–12, 2025 at the University of Lagos Guest Houses and Conference Centre, Akoka, Lagos, Nigeria.

Deadline – 10th December 2025

AI 4 Alzheimer's

This is a global online hackathon inviting developers and students to build AI-powered models aimed at early detection or improved diagnosis of Alzheimer's disease. Participants get access to de-identified biomedical data, mentorship, and the chance to compete for a substantial prize pool (around \$332,730 in prizes).

Deadline – 31st December 2025

Startup Support Grants by Luminate Foundation: Apply to Luminate 2026 | F6S

Luminate is a world-leading accelerator and investment portfolio supporting 10–12 emerging companies each year with a shared funding pool of \$3 million. It backs innovators developing cutting-edge solutions across almost every industry, from advanced manufacturing to healthcare and beyond. They are now seeking ambitious founders for Cohort 9. If your venture is redefining what's possible with next-generation technologies, this is a prime opportunity to scale with significant financial and programme support.

Deadline – 12th January 2026

Upcoming Events

1. The International AI Summit

Date: 11th December 2025.

Location: Brussels / Belgium

This summit convenes policymakers from the European Commission, the UN, and the WTO alongside global tech leaders (Microsoft, Accenture) to tackle the practical realities of AI governance. The agenda moves beyond theoretical ethics to address hard infrastructure needs energy, compute scarcity, and AI factories and the geopolitical race for digital sovereignty.

2. Afri Converse 2025

Date: 12th December 2025

Location: United Nations University 1F Annex Space (Hybrid format — in-person + zoom)

Co-organised by the UNDP and JICA, this discussion will unpack the new Human Resource Development Initiative which aims to train 30,000 African AI professionals, and explore how the continent can leapfrog legacy systems using locally governed AI. With speakers including UN University Rector Tshildtzi Marwala and innovators from the Matsuo Lab, this is a key forum for understanding the Japan-Africa investment corridor for digital skills and ecosystem funding.

3. Synopsis - The AI Engineering Conference

Date: 13th December 2025

Location: Lagos, Nigeria

This is a one-day deep-dive into “Software 2.0, Reliable AI Systems, and You!” The event explores the shift from traditional software to AI-powered systems, with talks and workshops on building, scaling and deploying reliable AI systems. Whether you’re a developer, data scientist or tech lead, it’s a solid opportunity to learn real-world AI-engineering practices and connect with fellow practitioners.
